## Database Management Systems

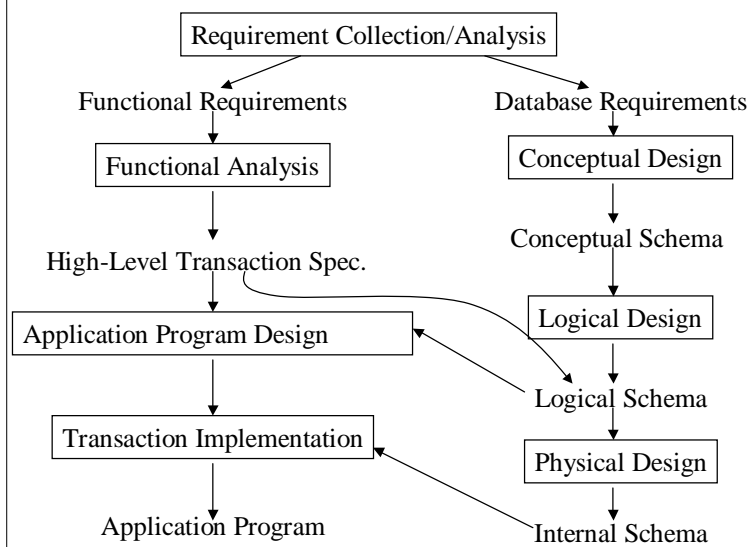

### Topic #4: Data Modeling

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

1

## Phases of Database Design

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

2

## Part A: Entity-Relationship Model

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

3

## What is ER Model About?

- Structure of the data
  - ◆ Entities and relationships between (among) entities
- Constraints
  - ◆ Conditions that the entities and relationships must satisfy.
  - ◆ Key constraint
  - ◆ Domain constraint
  - ◆ Structural constraint

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

4

## ER Concepts

- Entities
- Relationships
- Attributes

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

5

## Attributes

- Atomic vs. composite
- Single- vs. multivalued
- Stored vs. derived
- Complex Attributes

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

6

## Null Values

- Need
- Meanings
  - ◆ not applicable
  - ◆ unknown: missing or questionable existence

## Entities

- Entity type (intension): e.g., Employee or Dept
  - ◆ A *collection* of entities that have the same attributes
- Entity instance: e.g., Fred or Payroll
- Entity set (extension): e.g., {Fred, Bob, ...}

## Keys

- An intension corresponds to all possible extensions
- *Superkey*: a set of attributes that are unique for an entity type (i.e., for all possible extensions)
- *Key*: a minimal superkey—fewer attributes won't be unique
- An entity type may have multiple keys

## Relationships

- Relationship types: e.g., works-in
- Relationship instances: e.g., Fred works-in Payroll

## Relationship Properties

A relationship type

- associates entity types
- typically binary or ternary
- recursive
- may have attributes

## Entity Types

- Participate in relationship types
- Have roles in those relationship types

## Cardinality

Cardinality constraints: number of relationship instances in which an entity instance may feature

- 1:1
- 1:N
- M:N

## Achtung!

- Don't confuse 1:N with N:1
- Some notations, especially for O-O modeling, write the cardinalities differently

## Inferring Cardinalities

- We can construct paths between entity types
- These paths represent relationships composed from series of the existing relationships
- Their cardinalities can be inferred

## Fan Traps

- Situations where the inferred, i.e., implied, cardinality is weaker than the actual cardinality

## Participation

Participation constraints: whether each entity instance must feature in some relationship instance

- *total*: yes
- *partial*: no

## Chasm Traps

- When the composed relationship, i.e., path, has a weaker participation constraint than is actual

## Weak Entity Types

- No key of its own attributes
- Must participate in a total relationship
- Another participant of the relationship becomes the *owner*
- Key = owner's key + partial key

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

19

## Summary of ER Diagram Notations

	Entity
	Weak Entity
	Relationship
	Identifying Relationship
	Attribute
	Key Attribute
	Multi-valued Attribute

Spring 2002

20

## Summary of ER Diagram Notations

Composite Attribute

Derived Attribute

Total Participation  
of E2 in R

Cardinality Ratio  
1:N for E1:E2 In R

Structural Constraint (min,max)  
on Participation of E in R

## Part B: Enhanced ER Model

## Why Do We Need EER

- ER modeling is sufficient for representing many database schemas for “traditional” database applications.
- Recent applications require additional *semantic data modeling* concepts
  - ◆ Class/subclass relationship
  - ◆ Type inheritance
  - ◆ Specialization and generalization.

## Subclass-Superclass

- Subclasses:
  - ◆ Further refinement (grouping) of a (super)class
  - ◆ Attributes are inherited
  - ◆ Class/subclass relationship is different from the relationship in ER modeling.

## Specialization

- *Specialization*: The process of defining a set of subclasses of an entity type
  - ◆ Top-down conceptual refinement
  - ◆ Allows us to
    - ◆ Define a set of subclasses of an entity type
    - ◆ Establish additional specific attributes with each subclass
    - ◆ Establish additional specific relationship types between each subclass and other entity types or other subclasses.

## Generalization

- *Generalization*: creating a superclass by combining classes
  - ◆ bottom-up conceptual synthesis
  - ◆ Can be viewed as the inverse of the specialization process.

## Classification

- Predicate-based: when a defining predicate determines the subclass of which a given instance is member
- Attributed-based: when the predicate applies only on an attribute
- User-defined: when the user decide the subclass membership
- Disjoint vs. overlapping
- Total vs. partial

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

27

## Constraints on Specialization/Generalization

- Disjointness constraint
  - ◆ The subclasses of the specialization must be disjoint.
    - ◆ Specified by (d)
  - ◆ Otherwise, the subclasses may overlap.
    - ◆ Specified by (o)

Spring 2002

CSC 742: DBMS by Dr. Peng Ning

28

## Constraints on Specialization/Generalization

- Completeness constraint
  - ◆ Total Specialization
  - ◆ Partial Specialization
- Disjointness and completeness constraints are *independent*.
- Superclass identified from generalization is usually *total*.

## Rules

- Delete from superclass  $\Rightarrow$  delete from all subclasses
- Insert into predicate-based superclass  $\Rightarrow$  insert where predicate holds
- Insert into total superclass  $\Rightarrow$  insert into a subclass
  - ◆ can't reasonably be done unless a predicate is specified

## Structure

- *Hierarchy*: single inheritance
- *Lattice*: multiple inheritance
  - ◆ Shared subclass
- Attribute inheritance
  - ◆ Single inheritance: trivial
  - ◆ Multiple inheritance

## Union Types

- Category
  - ◆ A subclass of the Union of some entity types
  - ◆ A category has two or more super-classes
  - ◆ Different from generalization.

## Aggregation

- Combining objects to form a composite object.
- Three types of aggregations
  - ◆ Aggregate attribute values of an object to form the object
  - ◆ Represent an aggregation relationship as an ordinary relationship
  - ◆ Combine objects that are related by a relationship into a higher-level aggregate object.

## Association

- Associate objects from several *independent* classes.
- Not quite aggregation because deleting an entity instance doesn't destroy the instances it is composed of
